Symptoms, Negative Tests, and Periodicity in Parasitic Infections

Parasitological investigations of large patient populations are rarely conducted in the United States where the illusion of freedom from parasitic infections still predominate. Such investigations are considerably more common in most third world countries where endemic parasitosis are more readily documented.

Single and concurrent infections of 5 species of protozoans have been diagnosed in 378 symptomatic and asymptomatic patients from 644 samples examined in the summer of 1996 at the Diagnostic and Educational Laboratory (DEL) of the Phoenix based Institute of Parasitic Diseases (IPD) using a concentration-sedimentation technique (Amin, 1997). Fifty-four (8.4%) were infected with Blastocystis hominis, 13 (2.0%) with Cyclospora cayetanensis, 50 (7.8%) with Entamoeba coli, 53 (8.2%) with E. hartmanni, 99 (15.4%) with E. histolytica/E. dispar, 28 (4.3%) with Entamoeba spp., 9 (1.4%) with E. coli and E. hartmanni, 53 (8.2%) with B. hominis and Entamoeba spp., and 17 (2.6%) with other combinations of protozoan species. More females were represented in the infected, especially the multiply infected, patients than in the uninfected. The patient population varied between 0 and 78 years of age. Very young children were not multiply infected and only adults were infected with C. cayetanensis. All single and multiple infections were represented in symptomatic and asymptomatic patients. (Table 1)

Enteric and extra-intestinal symptoms were associated with presumably "harmless commensals" like E. coli and E. hartmanni. Symptomatic patients infected with E. histolytica/E. dispar markedly outnumbered those without symptoms.

It is clear from Table 1 that a number of patients had sub-clinical infections and showed no overt intestinal or extra-intestinal symptoms. These patients have been treated and their overall health improved after having been tested, and their parasites identified, at DEL-IPD.

Table 1. Prevalence of protozoan infections in stool samples of 644 symptomatic and asymptomatic patients examined during the summer of 1996 at DEL-IPD.

The most common intestinal symptoms include bloating, diarrhea, flatulence, cramps, constipation, maligestion, and malabsorption. Less frequently a patient may experience bleeding, irrigable bowel, ulcerative colitis, leaky gut, and excess mucus secretion. Extra-intestinal symptoms often include fatigue, allergies, nausea, nervous/sensory disorders (memory loss, brain fog, irritability, poor coordination), skin disorders, pain, and muscle problems. Less frequent extra-intestinal symptoms may include fever, headache, immune deficiency, insomnia, weight changes, respiratory and hepatic symptoms, and peritonitis.

It is also clear from Table 1 that a number of symptomatic patients had no parasites that were detectable from fecal samples provided. These cases are probably related to one or both of the following reasons:

1. Other pathogenic organisms, ex., pathogenic bacteria, can cause symptoms comparable to those produced by typical parasites. These may include enterotoxigenic Escherichia coli, Salmonella, Shigella and/or Campylobacter among others; see Paredes et al. (1996). Like the typical parasites, these bacterial parasites are also amenable to treatment with herbal products.

2. Because of the heterogeneous distribution and the cyclic nature of some of the most common human parasites, infections may not be detected in fecal samples if collected when parasites are not running in the main fecal flow; e.g., intervals of many days may intervene between amoebic "runs" which may make the microscopic examination of many stool specimens necessary to confirm a positive Entamoeba histolytica infection (Amin, 1994-95; Hiatt et al., 1995; Kelsall and Ravidin, 1994). The same kind of periodicity and/or adherence to the intestinal lining are also known to occur in Giardia lamblia (see Amin, 1994-95, Walterspiel and Pickering,
PECASOL® MODIFIED CITRUS PECTIN

The Heroic Orange

Citrus fruits have been heroes of health for years because of vitamin C.

PECASOL® MODIFIED CITRUS PECTIN:
A NEW HEALTH HERO
PECASOL® MODIFIED CITRUS PECTIN is a trademarked product that utilizes a special manufacturing process to enhance absorption and utilization of crucial polysaccharide compounds.

INHIBITION OF TUMOR GROWTH
Modified citrus pectin has been reported to inhibit metastasis in published literature by key researchers.

1995 STUDY CONCLUSION:
"...oral intake of modified citrus pectin acts as a potent inhibitor of spontaneous prostate carcinoma metastasis."

ECOGEN 851® FERMENTED SOY DRINK

The Prolific Soybean

Soy has been a staple food for centuries.
ECOGEN 851® IS A FERMENTED SOY DRINK
developed after ten years of culturing and selecting specific varieties of soybean. Fermentation transforms complex carbohydrates into simple sugars, proteins into amino acids, and the isoflavones into their free "active" form for optimal absorption. This adds up to optimal nutrition for those interested in maximum health.

POTENCY
97% of the isoflavones in ECOGEN 851® are present in their "free form" for ready absorption.

CRUCIAL IMMUNE ENHANCING COMPONENTS
Protease inhibitors and phytoestrogens found in soybeans are present in ECOGEN 851® in optimal levels. This drink combines the nutritional strengths of soy proteins with the concentrated phytochemicals and nutrients needed for health enhancement.
